Moral Hazard

EC 387 – Health Economics

Professor Pauline Mourot

Back to context

Grossman model (1972) of demand for *health*

Health:

- Enters utility directly
- Is a capital good individuals invest in
- It makes individuals more productive (less time sick)

What about the demand for ~~health~~ *healthcare*?

Some definitions

Moral hazard:

Moral hazard is the change in an individual's behavior that occurs after entering into a contract because the individual does not bear the full consequences of their actions, typically due to imperfect observability or enforcement.

Two types of moral hazard:

- **Ex-ante moral hazard** (Ehrlich and Becker, 1972): change in behavior *before* an event occurs (e.g., risk-taking)
- **Ex-post moral hazard** (Pauly, 1968): change in behavior *after* an event occurs (e.g., consumption of care)

Some definitions

Moral hazard:

Moral hazard is the change in an individual's behavior that occurs after entering into a contract because the individual does not bear the full consequences of their actions, typically due to imperfect observability or enforcement.

Two types of moral hazard:

- **Ex-ante moral hazard** (Ehrlich and Becker, 1972): change in behavior *before* an event occurs (e.g., risk-taking)
- **Ex-post moral hazard** (Pauly, 1968): change in behavior *after* an event occurs (e.g., consumption of care)

Examples of moral hazard

- Banks engaging in excessive risk-taking knowing that the government will bail them out
- Individuals driving recklessly when they have car insurance
- More generous unemployment insurance may cause some workers to remain out of work longer
- Academic researchers slacking off after tenure
- Individuals consuming more healthcare when they have health insurance

Examples of moral hazard

- Banks engaging in excessive risk-taking knowing that the government will bail them out
- Individuals driving recklessly when they have car insurance
- More generous unemployment insurance may cause some workers to remain out of work longer
- **Academic researchers slacking off after tenure**
- Individuals consuming more healthcare when they have health insurance

Economists after tenure

Moral hazard in healthcare

Gaining insurance: price of healthcare is lower $\rightarrow$ individuals consume more healthcare

$\Longrightarrow$ A rational response to an economic incentive?

$\Longrightarrow$ Isn't it simply the price elasticity of demand for *healthcare*?

History of the term "moral hazard"

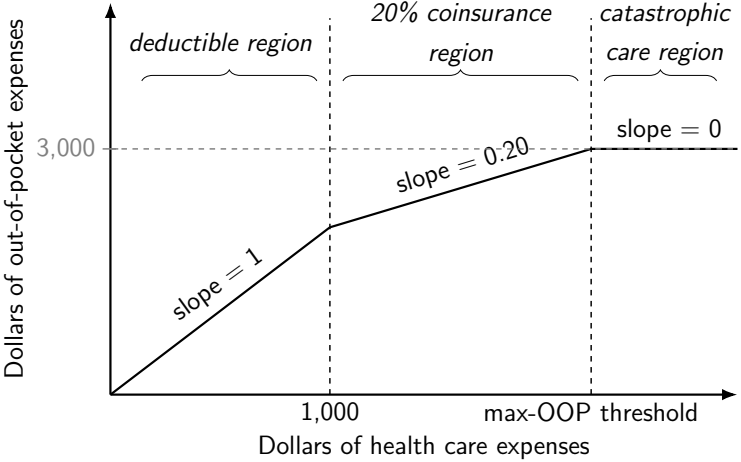
Kenneth Arrow (1963):*"the special economic problems of medical care can be explained by adaptations to uncertainty"*

Mark Pauly (1968): *"in addition to the issues of risk and uncertainty, insurers also have to anticipate how consumers will respond to the changes in the price of healthcare caused by insurance"*

- Explains that the term "moral hazard" comes from medical insurance writers describing "the hazard that arises from the failure of individuals who are or have been affected by insurance to uphold the accepted moral quantities"...
- ... but Pauly notes that "the response of seeking more medical care with insurance ... is a result not of moral perfidy, but of rational economic behavior"

Reminder from last week

Cost-sharing: portion of medical bill that the patient is responsible for paying



How to think about it?

Insurer chooses:

1. **Premium**: p
2. **Cost-sharing** (or coninsurance): s

Imagine the individual is sick and needs to pay $25,000 in medical bills with probability 0.2.

$\implies$ What is the insurer's problem?

$$\max_{p,s} p - 0.2 * (1 - s) * 25,000$$

such that

$$EU(\text{insured}) \geq EU(\text{not insured})$$

How to think about it?

Insurer chooses:

1. **Premium**: p
2. **Cost-sharing** (or coninsurance): s

Imagine the individual is sick and needs to pay $25,000 in medical bills with probability 0.2.

$\implies$ What is the insurer's problem?

$$\max_{p,s} p - 0.2 * (1 - s) * 25,000$$

such that

$$EU(\text{insured}) \geq EU(\text{not insured})$$

How to think about it?

Moral hazard: $d > 0$

$\implies$ The individual would consume $\$25,000 \times (1 + d \times s)$ in medical care if insured.

$\implies$ The insurer faces a trade-off:

- Higher $s \rightarrow$ less moral hazard $\rightarrow$ lower costs
- Higher $s \rightarrow$ less attractive insurance $\rightarrow$ lower premium

$\implies$ Is $d = 0$? If not, how large is it?

How to think about it?

Moral hazard: $d > 0$

$\implies$ The individual would consume $\$25,000 \times (1 + d \times s)$ in medical care if insured.

$\implies$ The insurer faces a trade-off:

- Higher $s \rightarrow$ less moral hazard $\rightarrow$ lower costs
- Higher $s \rightarrow$ less attractive insurance $\rightarrow$ lower premium

$\implies$ Is $d = 0$? If not, how large is it?

Back to basics of demand

Demand

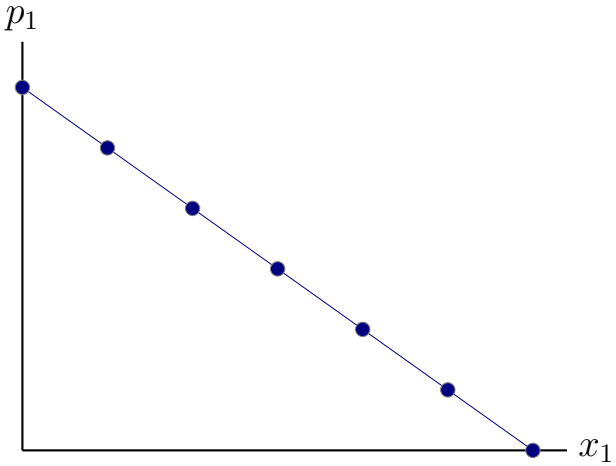
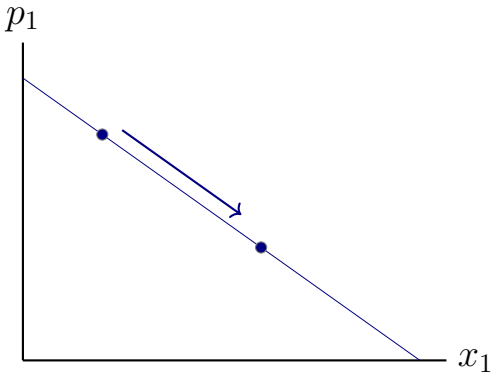
Demand



Move *along* the demand



Is the demand for healthcare different than other goods?

What is cost-sharing?

Cost-sharing: portion of medical bill that the patient is responsible for paying

Demand slopes **down**

1. Is this true in healthcare?
2. If so, to what extent?
3. What does this mean for insurance?

What is cost-sharing?

Cost-sharing: portion of medical bill that the patient is responsible for paying

Demand slopes **down**

1. Is this true in healthcare? **Late 70s: was a debate.**
2. If so, to what extent? *Elasticity of healthcare demand*
3. What does this mean for insurance?

The **RAND health insurance experiment**

Back to the late 70s in California...

Reading: the RAND health insurance experiment

The Health Insurance Experiment

A Classic RAND Study Speaks to the Current Health Care Reform Debate

After decades of evolution and experiment, the U.S. health care system has yet to solve a fundamental challenge: delivering quality health care to all Americans at an affordable price. In the coming years, new solutions will be explored and older ideas revisited. One idea that has returned to prominence is cost sharing, which involves shifting a greater share of health care expense and responsibility onto consumers. Recent public discussion of cost sharing has often cited a landmark RAND study: the Health Insurance Experiment (HIE). Although it was completed over two decades ago, in 1982, the HIE remains the only long-term, experimental study of cost sharing and its effect on service use, quality of care, and health. The purpose of this research brief is to summarize the HIE's main findings and clarify its relevance for today's debate.

Key findings:

- In a large-scale, multiyear experiment, participants who paid for a share of their health care used fewer health services than a comparison group given free care.
- Cost sharing reduced the use of both highly effective and less effective services in roughly equal proportions. Cost sharing did not significantly affect the quality of care received by participants.
- Cost sharing in general had no adverse effects on participant health, but there were exceptions: free care led to improvements in hypertension, dental health, vision, and selected serious symptoms. These improvements were concentrated among the sickest and poorest patients.

The **RAND health insurance experiment**

The **RAND health insurance experiment**

- Joe Newhouse (PI) at the RAND corporation
- 1974-1981: randomize $\approx$ 2,000 families into plans with **different cost-sharing**
- Duration of experiment: 3-5 years
- 6 enrollment sites
- Outcomes of interest: health spending and health

A pioneering study

- One of the largest experiments ($300 million in2011 dollars)
- Screening questionnaires
- The experiment **acts as your insurer**

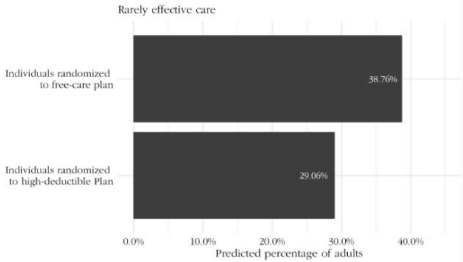
Which kind of care is consumed less?



This figure shows the percentage reduction in total healthcare consumed for "highly effective care" and "rarely effective care". These categories are defined by physicians based on their expert judgement about the average effectiveness of different types of care. For example, receiving medical care for some types of acute conditions (like bronchitis, vaginitis, or lacerations) is often highly effective; by contrast, receiving medical care for other types of acute conditions (e.g., sprains or strains) is rarely effective and can be managed with over-the-counter medication. The figure shows a similar percentage reduction in both types of healthcare when comparing families randomized into the high-deductible plans and the free-care plans. Simply put, deductibles cause families to cut back on both highly effective care and rarely effective care.

Simply put, deductibles cause families to cut back on both highly effective care and rarely effective care.

$\Longrightarrow$ Which care is cut? Both "rarely effective" and "effective" care.

Impact on health?

Impact on health?

Effects on Health

In general, the reduction in services induced by cost sharing had no adverse effect on participants' health. However, there were exceptions. The poorest and sickest 6 percent of the sample at the start of the experiment had better outcomes under the free plan for 4 of the 30 conditions measured. Specifically,

- Free care improved the control of *hypertension*. The poorest patients in the free care group who entered the experiment with hypertension saw greater reductions in blood pressure than did their counterparts with cost sharing. The projected effect was about a 10 percent reduction in mortality for those with hypertension.
- Free care marginally improved *vision* for the poorest patients.
- Free care also increased the likelihood among the poorest patients of receiving needed *dental care*.
- *Serious symptoms*[2] were less prevalent for poorer people on the free plan.
- Cost sharing also had some beneficial effects. Participants in cost sharing plans worried less about their health and had fewer restricted-activity days (including time spent in seeking medical care).

The **RAND health insurance experiment**: conclusion

Main results:

- Healthcare demand slopes down
- Insurance increases the demand for healthcare
- Which care is cut: both "effective" and "rarely effective" care
- Impact on health? None on average but poor adults are hurt

Legacy

- Largest and most expensive RCT in social science to date
- No impact on health: paved the way for cost-sharing (80s) and high-deductible plans (2000s)

What about deductibles?

Zarek's paper

Other ways to prevent moral hazard

Prior authorization (United Healthcare example)

Ordeals (Josh's paper)

If needed: other evidence of moral hazard: age 65

What does health insurance do?

OHIE (see week 1 slides NOTO + book chapter)

Wraping up

What we covered today

- Understanding an insurance plan
  - Cost-sharing features of plans: premium, deductible, coinsurance, out-of-pocket max
  - "Types of plans": HMO, PPO, HDHP
- Demand for insurance

  (willingness to pay, actuarially fair price, expected profit for insurer)

To next class

- **TO DO**
  1. **Mandatory reading**: Chapter Gross and Notowidigdo chapter 1.3 [reading 2]

     $\Longrightarrow$ **We will discuss in class**
  2. Review this class and past material $\Longrightarrow$ *questions on it?*

- Program for next class
  - Moral hazard (continue)
  - WHat does insurance do?
